Journal Club procedure

– During/after journal clubs: give the presenters some constructive feedback

Feedback form: 14.10. Redefining CpG islands using hidden Markov models

Presenters: Luca Widmer, Meret Mosimann, Adriano Martinelli

* Required

How would you rate the presenters' coverage of the topic? *

- ○ Poor
- ○ Fair
- ○ Good
- ○ Very Good
- ○ Excellent

How would you rate the presenters' knowledge of the topic? *

Slide from 30.09. (updated)

Journal club

Papers to be picked by 18.00 on 14th October; discuss it with Hubert and I.

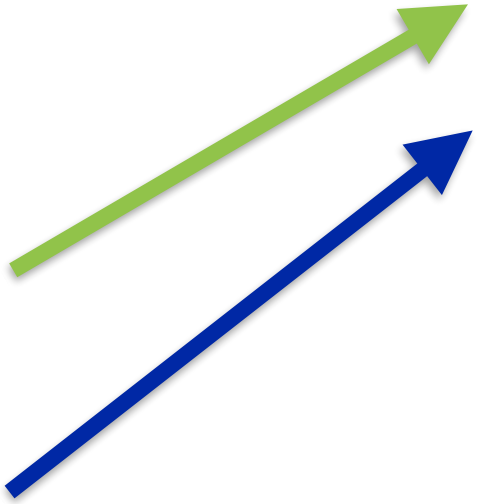
Start: Oct 14 or Oct 21

Journal Club schedule to be finalized by 21st October

Given the number of students, groups of 2-3.

Use the #journal-clubs channel (e.g., to find a group member). I have put a link to several suggestions there.

Sign up by pull request (give a link to the paper, give initials of group members)



14.10.2019	Mark	limma + friends	linear model simulation + design matrices	Redefining CpG islands using hidden Markov models (AM,LW,MM)	
21.10.2019	Hubert	RNA-seq quantification	RSEM		
28.10.2019	Kathi	hands-on session #1: RNA-seq	FASTQC/Salmon/etc.	X	X
04.11.2019	Mark	edgeR+friends 1	basic edgeR/voom		
11.11.2019	Mark	edgeR+friends 2	GLM/DEXSeq		
18.11.2019	Hubert	single-cell 1: preprocessing, dim. reduction, clustering	scRNA exercise 1	Integrating single-cell transcriptomic data across different conditions, technologies, and species (AA, HG)	Normalization of RNA-seq data using factor analysis of control genes or samples (J.M, F.H)
25.11.2019	Helena	hands-on session #2: cytometry	cytof null comparison	X	X
02.12.2019	Mark	single-cell 2: cell type definition, differential state	scRNA exercise 2	Capturing Heterogeneity in Gene Expression Studies by Surrogate Variable Analysis (C.B, T.F)	Molecular Cross-Validation for Single-Cell RNA-seq (AY, SM, GH)
09.12.2019	Pierre-Luc	hands-on session #3: single-cell RNA-seq	full scRNA-seq pipeline	X	X
16.12.2019	Mark	loose ends: HMM, EM, robustness	segmentation, peak finding	Shrinkage estimation of dispersion in Negative Binomial models for RNA-seq experiments with small sample size (AS, CP, IP)	

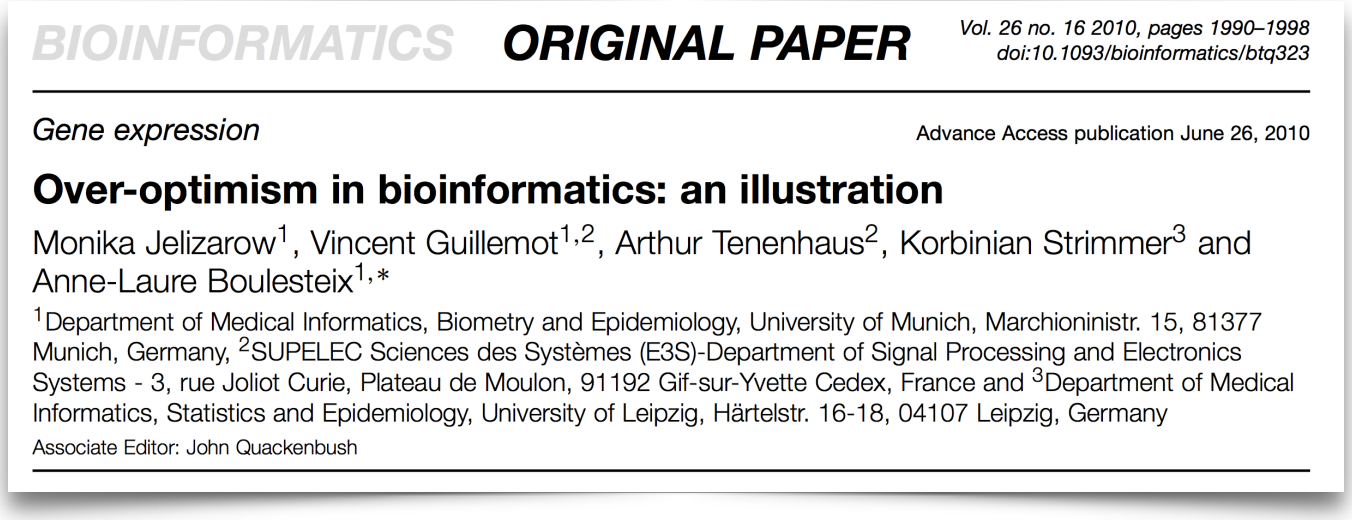
Journal clubs

– Presenters: please upload your slides to **#journal-clubs** channel

From the feed: "Over-optimism" + Terry's IMS Bulletin

We will see a lot of methods in this course – **how do we evaluate what works well in practice ?**

http://bulletin.imstat.org/2012/11/terences-stuff-does-it-work-in-practice/



BIOINFORMATICS **ORIGINAL PAPER**

Vol. 26 no. 16 2010, pages 1990–1998
doi:10.1093/bioinformatics/btq323

Gene expression

EDITORIAL

Ten Simple Rules for Reducing Overoptimistic Reporting in Methodological Computational Research

Anne-Laure Boulesteix*

Institute for Medical Informatics, Biometry and Epidemiology, Ludwig Maximilians University, Munich, Germany

* boulesteix@ibe.med.uni-muenchen.de

"if the improvement of a quantitative criterion such as the error rate is the main contribution of a paper, the superiority of new algorithms should always be demonstrated on independent validation data."

In class exercise + discussion

- (5 minutes) Read the excerpt from “Terence’s Stuff” column
- (5-10 minutes; discuss with your neighbour) Answer the following 4 questions:
  1. How do we tell what works in practice?
  2. What problems arise using simulated (synthetic) data?
  3. What problems arise using real data?
  4. What are positive/negative controls?
- Discuss
- If simulation: what metrics could/should we use?
- **n.b. include this method comparison context in your Journal Club talks**

=> simulated data is generated based on assumption ⇔ normal dist.

=> we don't have ground truth, maybe certain groups are missing

=> spike in data

limma fundamentals

Differential expression, small sample inference

- Table of data (e.g., microarray gene expression data with replicates of each of condition A, condition B)
  - rows = features (e.g., genes), columns = experimental units (samples)
- Most common problem in statistical bioinformatics: want to infer whether there is a change in the response —> a statistical test for each row of the table.

What test might you use? Why is this hard? What issues arise? How much statistical power is there [1] ?

replicates replicates

```

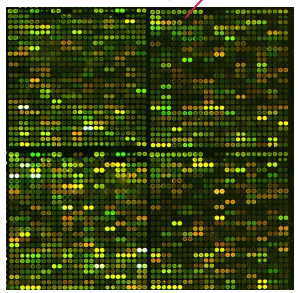
⇒ strictly underpowered due to sample size and # of genes

[1] http://www.stat.ubc.ca/~rollin/stats/ssize/n2.html

Microarray expression measures

Two-colour



2 color array

$$y_{ga} = \log_2(R/G)$$

array

probe or gene

⇒ log ratio of dye 1 and dye 2 intensities

Affymetrix

y_{ga} = log-intensity (summarized over probes)

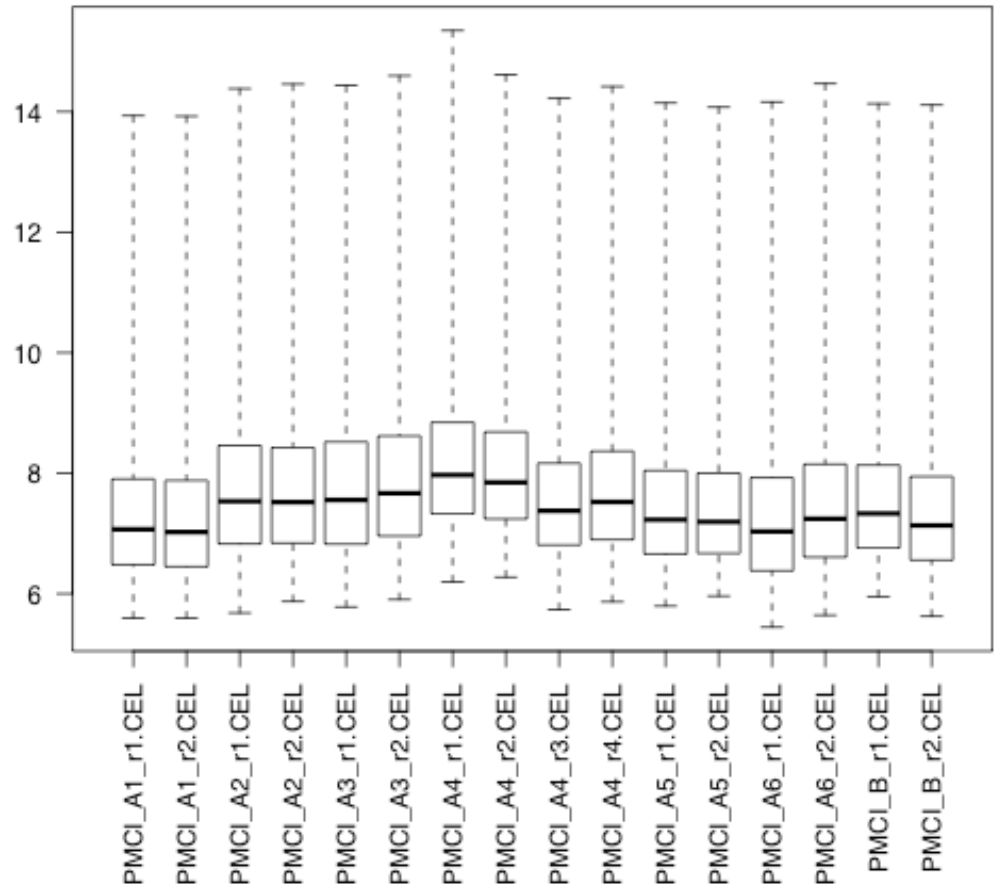
Illumina

y_{ga} = log-intensity (summarized over beads)

Normalization: one-colour

Similarly for single channel data, adjustments need to be made for all samples to be comparable.

⇒ Shifts in the distribution due to used chips and day of experiment
⇒ Quantil - Quantil normalisation



Preprocessing: additive + multiplicative error model

Observe intensity for one probe on one array

Intensity = background + signal

$$I = B + S$$

additive errors

multiplicative errors

This idea underlies variance stabilizing transformations vsn (two colour data) and vst (for Illumina data)

normexp convolution model

Microarray background correction: maximum likelihood estimation for the normal–exponential convolution

JEREMY D. SILVER
Bioinformatics Division, Walter and Eliza Hall Institute, Parkville 3050, Victoria, Australia and Department of Biostatistics, University of Copenhagen, Øster Farimagsgade 5, Entrance B, PO Box 2099, DK-1014 Copenhagen K, Denmark
j.silver@biostat.ku.dk
MATTHEW E. RITCHIE

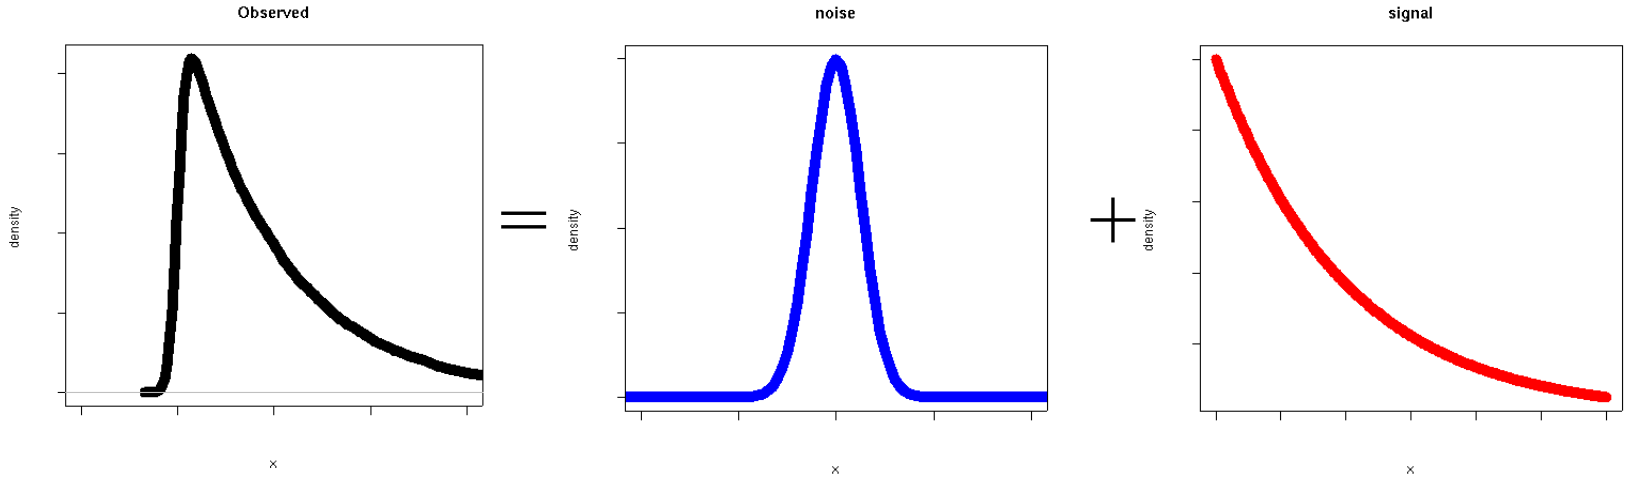
GORDON K. SMYTH*
Bioinformatics Division, Walter and Eliza Hall Institute, Parkville 3050, Victoria, Australia
smyth@wehi.edu.au

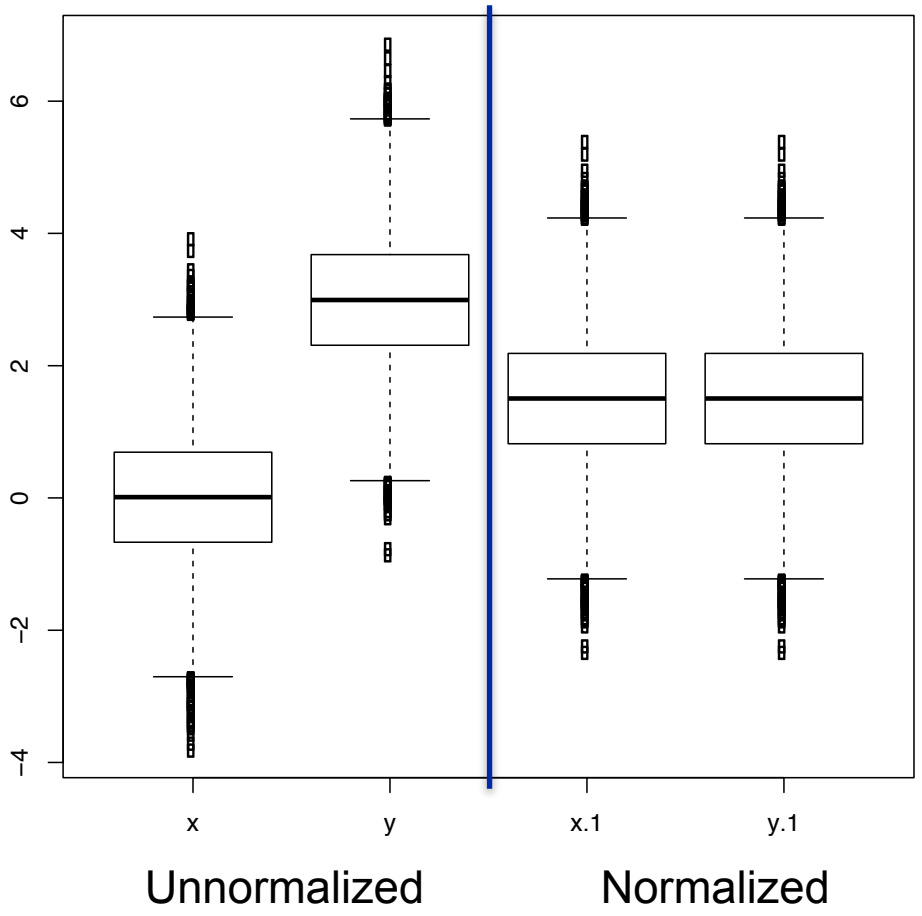
Intensity = Background + Signal

$N(\mu,\sigma^2)$ Exponential(α) ⇒ convolution of normal & exponential



⇒ for each feature you take the average & you obtain a distribution of this values. We force that the samples to follow this distribution but keep their relative order

Quantile normalization



```
x <- rnorm(10000, mean=0, sd=1)
y <- rnorm(10000, mean=3)
z <- cbind(x,y)

# create "reference" distribution
s <- apply(z,2,sort)
sm <- rowMeans(s)

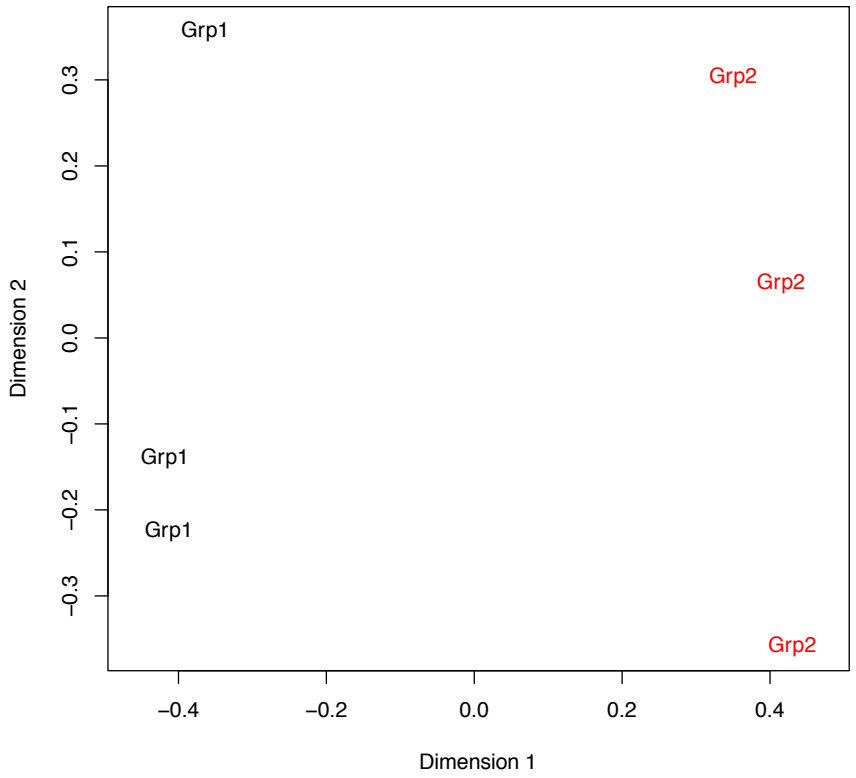
# impose ref. distribution by ranks
r <- apply(z,2,rank)
n <- apply(r,2,function(u) sm[u])

boxplot( data.frame(x=x,y=y,n) )

#> library(limma)
#> zn <- normalizeQuantiles(z)
#> all(zn==n)
#[1] TRUE
```

Quality assessments

Multidimensional scaling plot



```
sd <- 0.3*sqrt(4/rchisq(1000,df=4))
x <- matrix(rnorm(1000*6,sd=sd),1000,6)
x[1:50,4:6] <- x[1:50,4:6] + 2

mds <- plotMDS(x)

> round(mds$distance.matrix,3)
      [,1]  [,2]  [,3]  [,4] [,5] [,6]

```

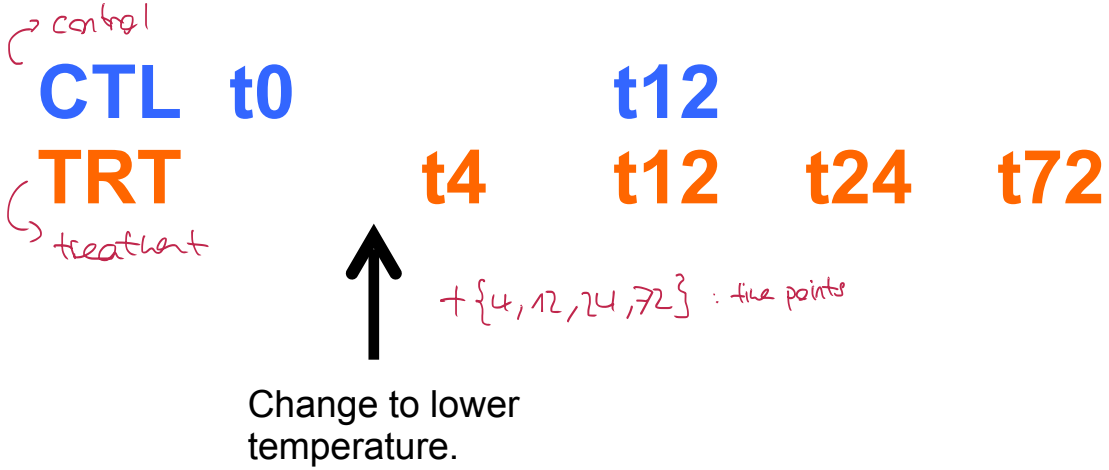
"To consult the statistician after an experiment is finished is often merely to ask him[her] to conduct a post mortem examination. He[She] can perhaps say what the experiment died of." R. A. Fisher

Motivation for exploratory data analysis: Case Study

(from Stefano, a former M.Sc. student in my Institute)

He is studying gene expression in fruitfly and is interested in transcriptional responses following "heat shock".

Basic schematic of experiment:



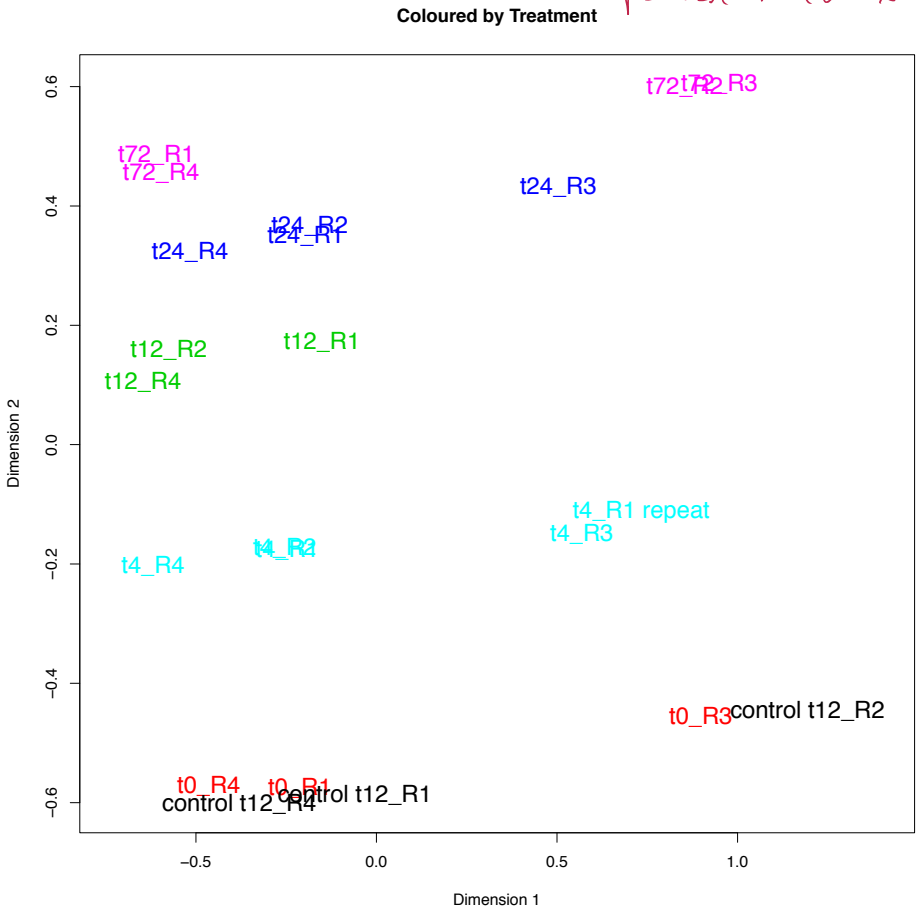
~4 replicates for each condition

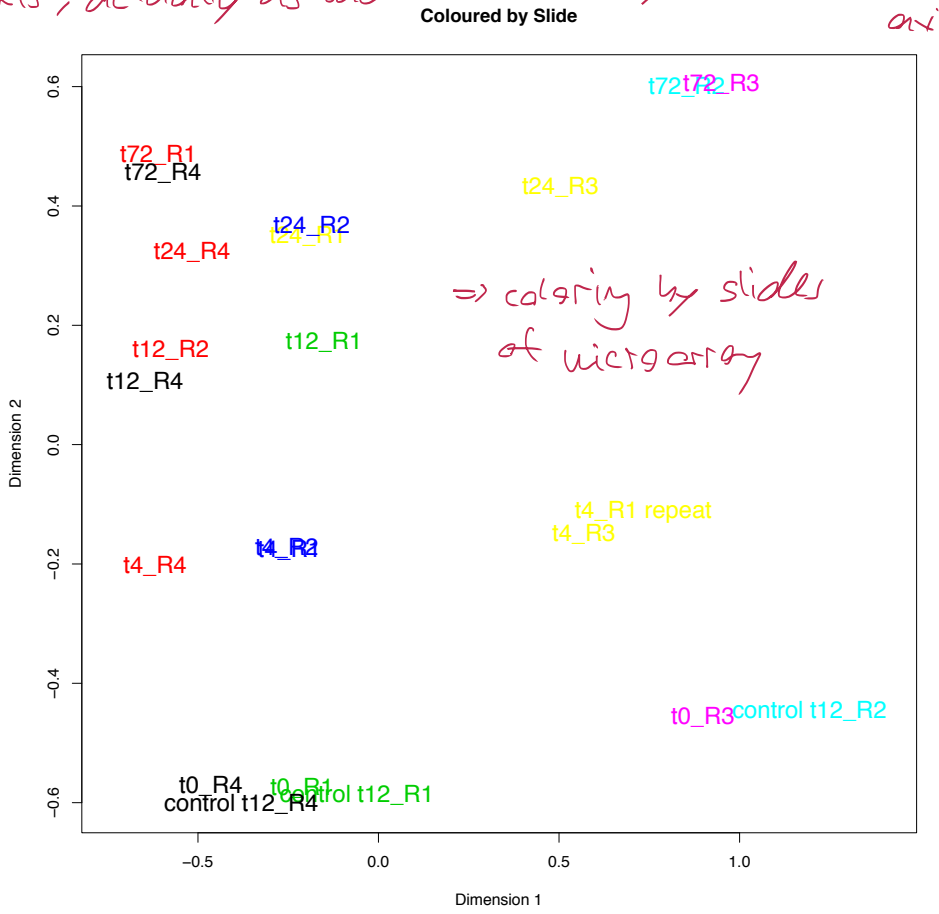
http://en.wikipedia.org/wiki/Multidimensional_scaling

```
library(limma)
plotMDS(d)  # 'd' is a matrix
```

Take a close look at where the replicates are to each other relative to the X- and Y-axes

=> We can see that the timepoint replicates cluster together
=> Lot of spread in the x-axis, actually as much as in the y-axis => The biologically relevant axis is y-axis since it separates the time points





=> coloring by slides of microarray

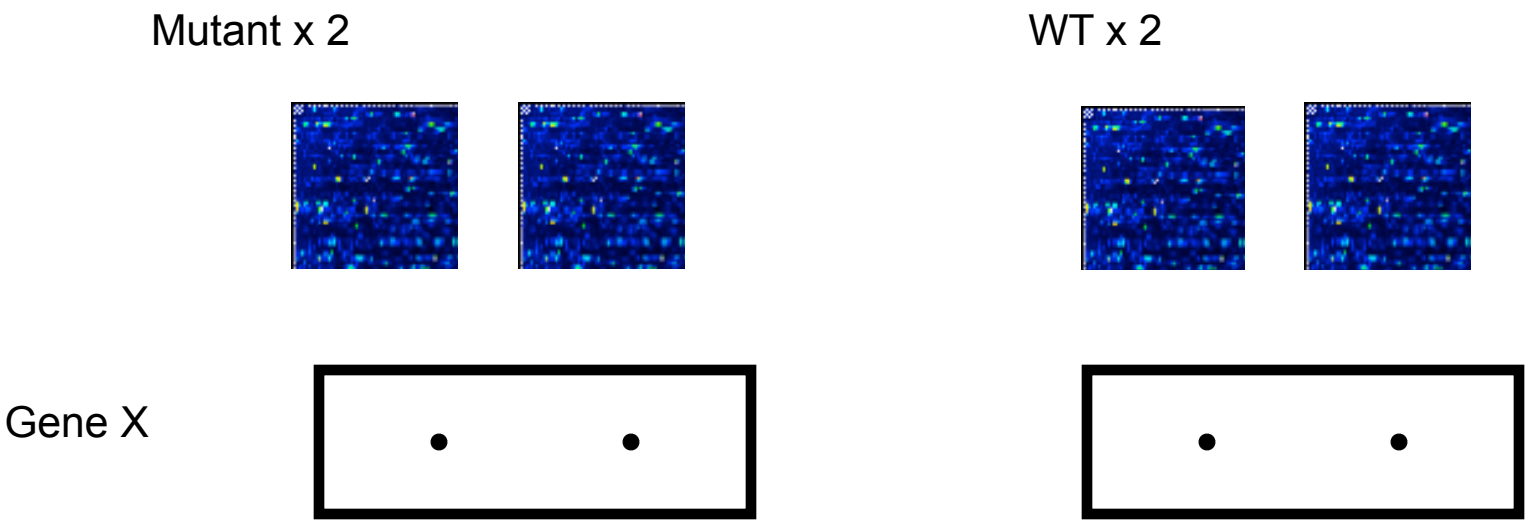
22 samples x ~20,000 genes

reduced to 22 samples x 2 dimensions

Limma concept: borrowing information across genes

- Small data sets: few samples, generally under-powered for 1 gene
- Curse of dimensionality: many tests, need to adjust for multiple testing (= loss of power)
- Benefit of parallelism: same model is fit for every gene. Can borrow information from one gene to another
  - Hard: assume parameters are constant across genes
  - Soft: smooth genewise parameters towards a common value in a graduated way, e.g., Bayes, empirical Bayes, Stein shrinkage …

A very common experiment (1-colour)



Which genes are differentially expressed?

$n_1 = n_2 = 2$ Affymetrix arrays

~30,000 probe-sets

Ordinary t-tests (1-colour)

⇒ With such a small sample it is hard to estimate the variation.

$$t_g = \frac{\overline{y}_{\text{mu}} - \overline{y}_{\text{wt}}}{s_g c}$$

↳ only for gene g ⇒ we have only 2 samples per condition

give very high false discovery rates

$$c = \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

Residual df = 2

t-tests with common variance

⇒ If we assume the variance of each gene is the same we get a better estimate

$$t_{g,\text{pooled}} = \frac{\overline{y}_{\text{mu}} - \overline{y}_{\text{wt}}}{s_0\, c}$$

with residual standard deviation s_0 pooled

across genes

More stable, but ignores gene-specific variability

↳ problem if certain genes are more tightly regulated than others.

$$c = \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

A better compromise

Proposal that we weight $\{d_0, d_g\}$ a global variance s_0 and a gene-specific variance

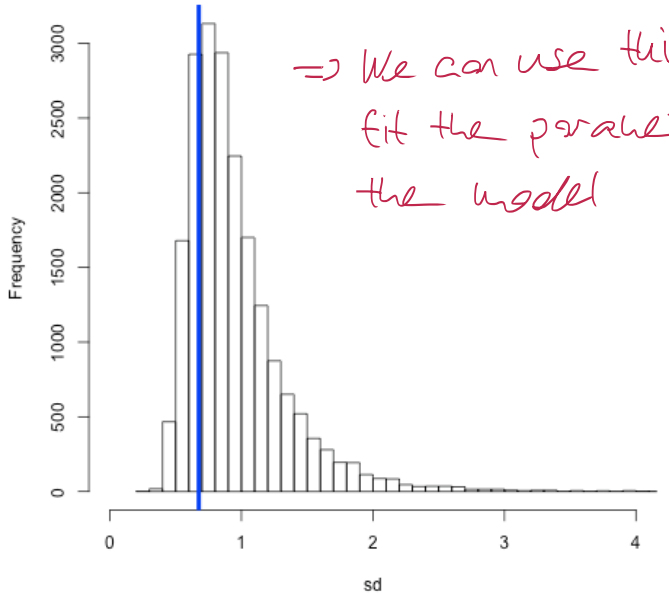
Shrink standard deviations towards common value

$$\tilde{s}_g^2 = \frac{d_0 s_0^2 + d_g s_g^2}{d_0 + d_g}$$

d = degrees of freedom

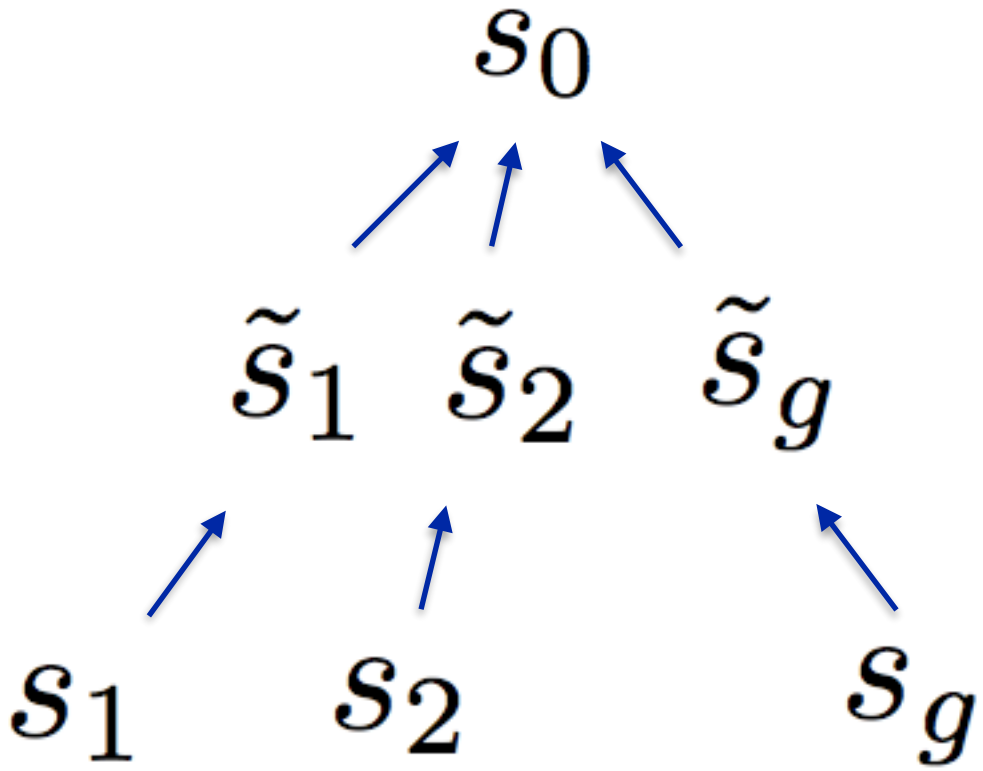
Moderated t-statistics

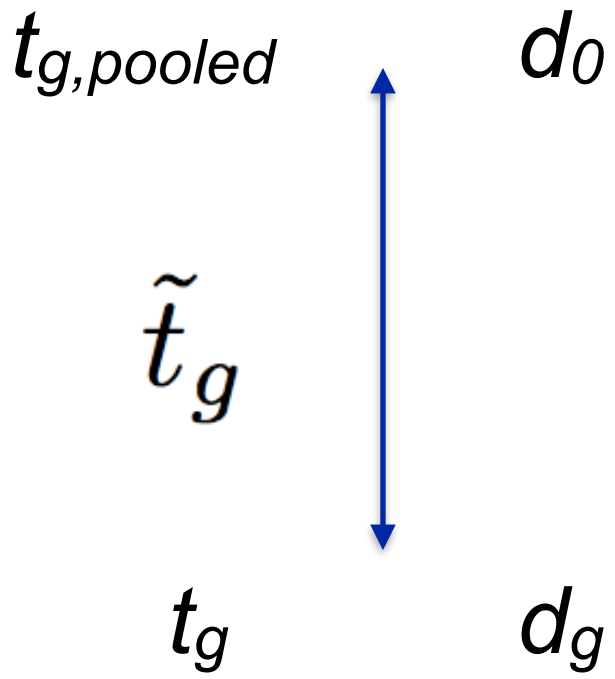
$$\tilde{t}_g = \frac{\overline{y}_{\text{mu}} - \overline{y}_{\text{wt}}}{\tilde{s}_g \, u}$$



⇒ We can use this distribution to fit the parameter d_0 for the model

Shrinkage of standard deviations





The **data decides** whether $\tilde{t}_g$ should be closer to $t_{g,pooled}$ or t_g

Why does it work?

- We learn what is the typical variability level by looking at all genes, but allow some flexibility from this for individual genes
- Adaptive – data (through hyperparameter estimates, d_0 and s_0) suggests how much to “squeeze” toward common value

Hierarchical model for variances

observed std

true std

⇒ observed std distribution comes from a χ^2 distribution

Data

$$s_g^2 \sim \sigma_g^2 \frac{\chi^2_{d_g}}{d_g}$$

Prior

$$\frac{1}{\sigma_g^2} \sim s_0^2 \frac{\chi^2_{d_0}}{d_0}$$

Posterior

$$E\left(\frac{1}{\sigma_g^2} \mid s_g^2\right) = \frac{d_0 + d_g}{s_0^2 d_0 + s_g^2 d_g}$$

precision parameter

Posterior Statistics

Posterior variance estimators

$$\tilde{s}_g^2 = \frac{s_0^2 d_0 + s_g^2 d_g}{d_0 + d_g}$$

Moderated t-statistics

$$\tilde{t}_{gj} = \frac{\hat{\beta}_{gj}}{\tilde{s}_g \sqrt{c_{gj}}}$$

→ β from a linear model

a the group t-test is equivalent to performing a linear model in which a parameter reflects the shift in mean

Baldi & Long 2001, Wright & Simon 2003, Smyth 2004

Exact distribution for moderated t

An unexpected piece of mathematics shows that, under the null hypothesis,

$$\tilde{t}_g \sim t_{d_0+d_g}$$

} "adding samples" by using this model

The degrees of freedom add!

The Bayes prior in effect adds d_0 extra arrays for estimating the variance.

Wright and Simon 2003, Smyth 2004

Aside: Marginal Distributions to calculate

Under usual likelihood model, s_g is independent of the estimated coefficients.

Under the hierarchical model, s_g is independent of the moderated t-statistics instead

$$s_g^2 \sim s_0^2 F_{d,d_0}$$

Multiple testing and adjusted p-values

- Each statistical test has an associated false positive rate
- Traditional method in statistics is to control family wise error rate, e.g., by Bonferroni. => controlling the probably of any false positive
- Controlling the false discovery rate (FDR) is more **appropriate** in microarray studies => control the proportion of errors in the positives
- Benjamini and Hochberg method controls expected FDR for independent or weakly dependent test statistics. Simulation studies support use for genomic data.
- All methods can be implemented in terms of adjusted p-values.

Linear Models

- In general, need to specify:
  - Dependent variable
  - Explanatory variables (experimental design, covariates, etc.)
- More generally:

$$y = X\beta + \epsilon$$

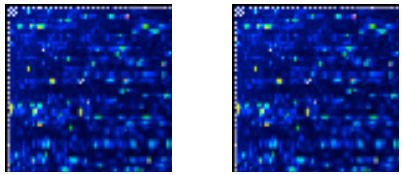
vector of observed data

design matrix

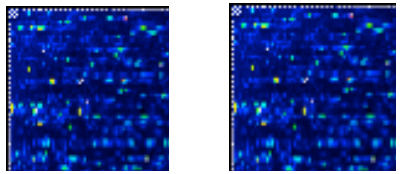
Vector of parameters to estimate

Design → Linear models

WT x 2



Mutant x 2



$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 1 & 0 \\ 1 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \end{bmatrix}$$

β_1 = wt log-expression

β_2 = mutant – wt

→ reflects difference between wt & mutant

$E[y_1]=E[y_2]=\beta_1$ $E[y_3]=E[y_4]=\beta_1+\beta_2$

Layers to add ..

- Where does the moderated variance come from?
- Why the degrees of freedom add: $d_0 + d$
- empirical Bayes: how to estimate the hyperparameters (d_0 and s_0)
- Design matrices + contrast matrices in practice

Unexpected mathematics: Why do degrees of freedom add?

The construction of the classical t-statistic:

$$Z = \left(\overline{X}_n - \mu\right) \frac{\sqrt{n}}{\sigma}$$

$$V = (n-1)\frac{S_n^2}{\sigma^2}$$

$$T \equiv \frac{Z}{\sqrt{V/\nu}} = \left(\overline{X}_n - \mu\right) \frac{\sqrt{n}}{S_n},$$

Stated another way → Exercise (optional): what are a, b above?

If T is distributed as $(a/b)^{1/2}Z/U$ where $Z \sim N(0,1)$ and $U \sim \chi_\nu$, then T has density function

$$p(t) = \frac{a^{\nu/2}b^{1/2}}{B(1/2,\nu/2)(a+bt^2)^{1/2+\nu/2}}$$

http://en.wikipedia.org/wiki/Bayesian_inference

Optional exercise: Derive the posterior

Data

$$s_g^2 \sim \sigma_g^2 \frac{\chi^2_{d_g}}{d_g}$$

Prior

$$\frac{1}{\sigma_g^2} \sim s_0^2 \frac{\chi^2_{d_0}}{d_0}$$

$$p(\theta|x) = \frac{f(x|\theta)p(\theta)}{\int f(x|\theta)p(\theta)d\theta}$$

Posterior

$$E\left(\frac{1}{\sigma_g^2} \mid s_g^2\right) = \frac{d_0 + d_g}{s_0^2 d_0 + s_g^2 d_g}$$

→ expected value of posterior

Optional exercise
Sketch: i) Let $x=s^2$, $\theta=\sigma^{-2}$; ii) Using the functional form of chi-squared distribution, calculate only the numerator (since denominator does not contain θ); iii) collect terms and see if you can identify the distribution and the parameters of it; iv) What is the mean of this distribution?

Linear Models

- In general, need to specify:
  - Dependent variable
  - Explanatory variables (experimental design, covariates, etc.)
- More generally:

$$y = X\alpha + \epsilon$$

vector of observed data

design matrix

Vector of parameters to estimate

Obtain a linear model for each gene g

$$E(\underset{\sim}{y}_g) = X\underset{\sim}{\alpha}_g$$

$$\mathrm{var}(\underset{\sim}{y}_g) = W_g^{-1}\sigma_g^2$$

Contrasts -- `contrasts.fit()`

A *contrast* is any linear combination of the coefficients α_j which we want to test equal to zero.

Define contrasts

$$\underset{\sim}{\beta}_g = C^T \underset{\sim}{\alpha}_g$$

were C is the contrast matrix.

Want to test

$$H_0 : \beta_{gj} = 0$$

vs

$$H_a : \beta_{gj} \neq 0$$

Unexpected mathematics: Why do degrees of freedom add?

→ Distribution under H_0

$$p(\hat{\beta}, s^2 \mid \beta = 0) = \int p(\hat{\beta} \mid \sigma^{-2}, \beta = 0)\, p(s^2 \mid \sigma^{-2})\, p(\sigma^{-2})\, d(\sigma^{-2})$$

The integrand is

$$\frac{1}{(2\pi v\sigma^2)^{1/2}} \exp\left(-\frac{\hat{\beta}^2}{2v\sigma^2}\right)$$

$$\times \left(\frac{d}{2\sigma^2}\right)^{d/2} \frac{s^{2(d/2-1)}}{\Gamma(d/2)} \exp\left(-\frac{ds^2}{2\sigma^2}\right)$$

$$\times \left(\frac{d_0 s_0^2}{2}\right)^{d_0/2} \frac{\sigma^{-2(d_0/2-1)}}{\Gamma(d_0/2)} \exp\left(-\sigma^{-2}\frac{d_0 s_0^2}{2}\right)$$

$$= \frac{(d_0 s_0^2/2)^{d_0/2}(d/2)^{d/2} s^{2(d/2-1)}}{(2\pi v)^{1/2}\Gamma(d_0/2)\Gamma(d/2)}$$

$$\sigma^{-2(1/2+d_0/2+d/2-1)} \exp\left\{-\sigma^{-2}\left(\frac{\hat{\beta}^2}{2v} + \frac{ds^2}{2} + \frac{d_0 s_0^2}{2}\right)\right\}$$

Unexpected mathematics: Why do degrees of freedom add?

$$p(\hat{\beta}, s^2 \mid \beta = 0) = \int p(\hat{\beta} \mid \sigma^{-2}, \beta = 0) p(s^2 \mid \sigma^{-2}) p(\sigma^{-2}) d(\sigma^{-2})$$

$$= \frac{(d_0 s_0^2/2)^{d_0/2} (d/2)^{d/2} s^{2(d/2-1)}}{(2\pi v)^{1/2} \Gamma(d_0/2) \Gamma(d/2)}$$

$$\sigma^{-2(1/2+d_0/2+d/2-1)} \exp\left\{-\sigma^{-2}\left(\frac{\hat{\beta}^2}{2v} + \frac{ds^2}{2} + \frac{d_0 s_0^2}{2}\right)\right\}$$

σ^{-2} is chi-squared (or gamma)

$$f(x; k) = \begin{cases} \frac{x^{(k/2)-1} e^{-x/2}}{2^{k/2}\Gamma\left(\frac{k}{2}\right)}, & x \geq 0; \\ 0, & \text{otherwise.} \end{cases}$$

http://en.wikipedia.org/wiki/Chi-squared_distribution

Unexpected mathematics: Why do degrees of freedom add?

$$p(\hat{\beta}, s^2 \mid \beta = 0) = \int p(\hat{\beta} \mid \sigma^{-2}, \beta = 0) p(s^2 \mid \sigma^{-2}) p(\sigma^{-2}) d(\sigma^{-2})$$

$$p(\hat{\beta}, s^2 \mid \beta = 0)$$
$$= \frac{(1/2v)^{1/2} (d_0 s_0^2/2)^{d_0/2} (d/2)^{d/2} s^{2(d/2-1)}}{D(1/2, d_0/2, d/2)} \left(\frac{\hat{\beta}^2/v + d_0 s_0^2 + d s^2}{2} \right)^{-(1+d_0+d)/2}$$

Unexpected mathematics: Why do degrees of freedom add?

$$p(\hat{\beta}, s^2 \mid \beta = 0) = \frac{(1/2v)^{1/2}(d_0 s_0^2/2)^{d_0/2}(d/2)^{d/2} s^{2(d/2-1)}}{D(1/2, d_0/2, d/2)} \left(\frac{\hat{\beta}^2/v + d_0 s_0^2 + d s^2}{2} \right)^{-(1+d_0+d)/2}$$

The null joint distribution of $\tilde{t}$ and s^2 is

$$p(\tilde{t}, s^2 \mid \beta = 0) = \tilde{s} v^{1/2} p(\hat{\beta}, s^2 \mid \beta = 0)$$

http://en.wikipedia.org/wiki/Random_variable#Distribution_functions_of_random_variables

$$f_Y(y) = f_X(g^{-1}(y)) \left| \frac{dg^{-1}(y)}{dy} \right|$$

Unexpected mathematics: Why do degrees of freedom add?

If T is distributed as $(a/b)^{1/2}Z/U$ where $Z \sim N(0,1)$ and $U \sim \chi_\nu$, then T has density function

$$p(t) = \frac{a^{\nu/2}b^{1/2}}{B(1/2,\nu/2)(a+bt^2)^{1/2+\nu/2}}$$

$$p(\tilde{t}, s^2 \mid \beta = 0) = \frac{(d_0 s_0^2)^{d_0/2} d^{d/2} s^{2(d/2-1)}}{B(d/2, d_0/2)(d_0 s_0^2 + d s^2)^{d_0/2+d/2}} \Rightarrow \text{only dependent on } s^2$$

$$\times \frac{(d_0+d)^{-1/2}}{B(1/2, d_0/2+d/2)} \left(1 + \frac{\tilde{t}^2}{d_0+d}\right)^{-(1+d_0+d)/2} \Rightarrow \text{only dependent on } \tilde{t}^2$$

$\Leftrightarrow \tilde{t}^2, s^2$ are independent since the show up in two different sums

This shows that $\tilde{t}$ and s^2 are independent with

$$s^2 \sim s_0^2 F_{d,d_0}$$

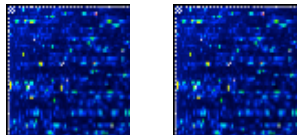
and

$$\tilde{t} \mid \beta = 0 \sim t_{d_0+d}.$$

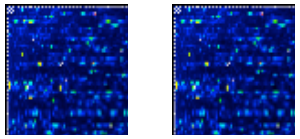
↳ degrees of freedom add under the null hypothesis

Analysis of Variance → Linear model

WT x 2



Cond A x 2



Cond B x 2

$$\beta = C\alpha = \begin{bmatrix} -1 & 1 & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = \begin{bmatrix} \alpha_2 - \alpha_1 \\ \alpha_3 - \alpha_2 \end{bmatrix}$$

Contrasts -- `contrasts.fit()`

A *contrast* is any linear combination of the coefficients α_j which we want to test equal to zero.

Define contrasts

$$\underset{\sim}{\beta}_g = C^T \underset{\sim}{\alpha}_g$$

were C is the contrast matrix.

Want to test

$$H_0 : \beta_{gj} = 0$$

vs

$$H_a : \beta_{gj} \neq 0$$

Limma / Analysis of Variance

$$F = \frac{\text{variance between treatments}}{\text{variance within treatments}}$$

$$F = \frac{MS_{\text{Treatments}}}{MS_{\text{Error}}} = \frac{SS_{\text{Treatments}}/(I-1)}{SS_{\text{Error}}/(n_T - I)}$$

The moderated t-statistics also lead naturally to moderated F-statistics which can be used to test hypotheses about any set of contrasts simultaneously. Appropriate quadratic forms of moderated t-statistics follow F-distributions just as do quadratic forms of ordinary t-statistics. Suppose that we wish to test all contrasts for a given gene equal to zero, i.e., $H_0 : \boldsymbol{\beta}_g = 0$. The correlation matrix of $\hat{\boldsymbol{\beta}}_g$ is $R_g = U_g^{-1} C^T V_g C U_g^{-1}$ where U_g is the diagonal matrix with unscaled standard deviations $(v_{gj})^{1/2}$ on the diagonal. Let r be the column rank of C. Let Q_g be such that $Q_g^T R_g Q_g = I_r$ and let $\mathbf{q}_g = Q_g^T \mathbf{t}_g$. Then

$$F_g = \mathbf{q}_g^T \mathbf{q}_g / r = \mathbf{t}_g^T Q_g Q_g^T \mathbf{t}_g / r \sim F_{r, d_0 + d_g}$$

Aside: Marginal Distributions to calculate

Fun fact: Under usual likelihood model, s_g is independent of the estimated coefficients.

Under the hierarchical model, s_g is independent of the moderated t-statistics instead

$$s_g^2 \sim s_0^2 F_{d,d_0}$$

Thus, the set of s_g can be used to estimated d_0 and s_0

Section 6.2 limma paper: other tricks, such as Fisher's z distribution to estimate d_0 and s_0

Relate to limma objects

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \\ y_6 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \\ \epsilon_4 \\ \epsilon_5 \\ \epsilon_6 \end{bmatrix}$$

$E[y_1]=E[y_2]=\alpha_1$
$E[y_3]=E[y_4]=\alpha_2$
$E[y_5]=E[y_6]=\alpha_3$

$$\beta = C\alpha = \begin{bmatrix} -1 & 1 & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = \begin{bmatrix} \alpha_2 - \alpha_1 \\ \alpha_3 - \alpha_2 \end{bmatrix}$$
